

Coherence ~ Rupture ~ Regeneration

A Temporal Grammar

The present ("now") is the critical transition point where the settled past collapses to open up future possibilities.

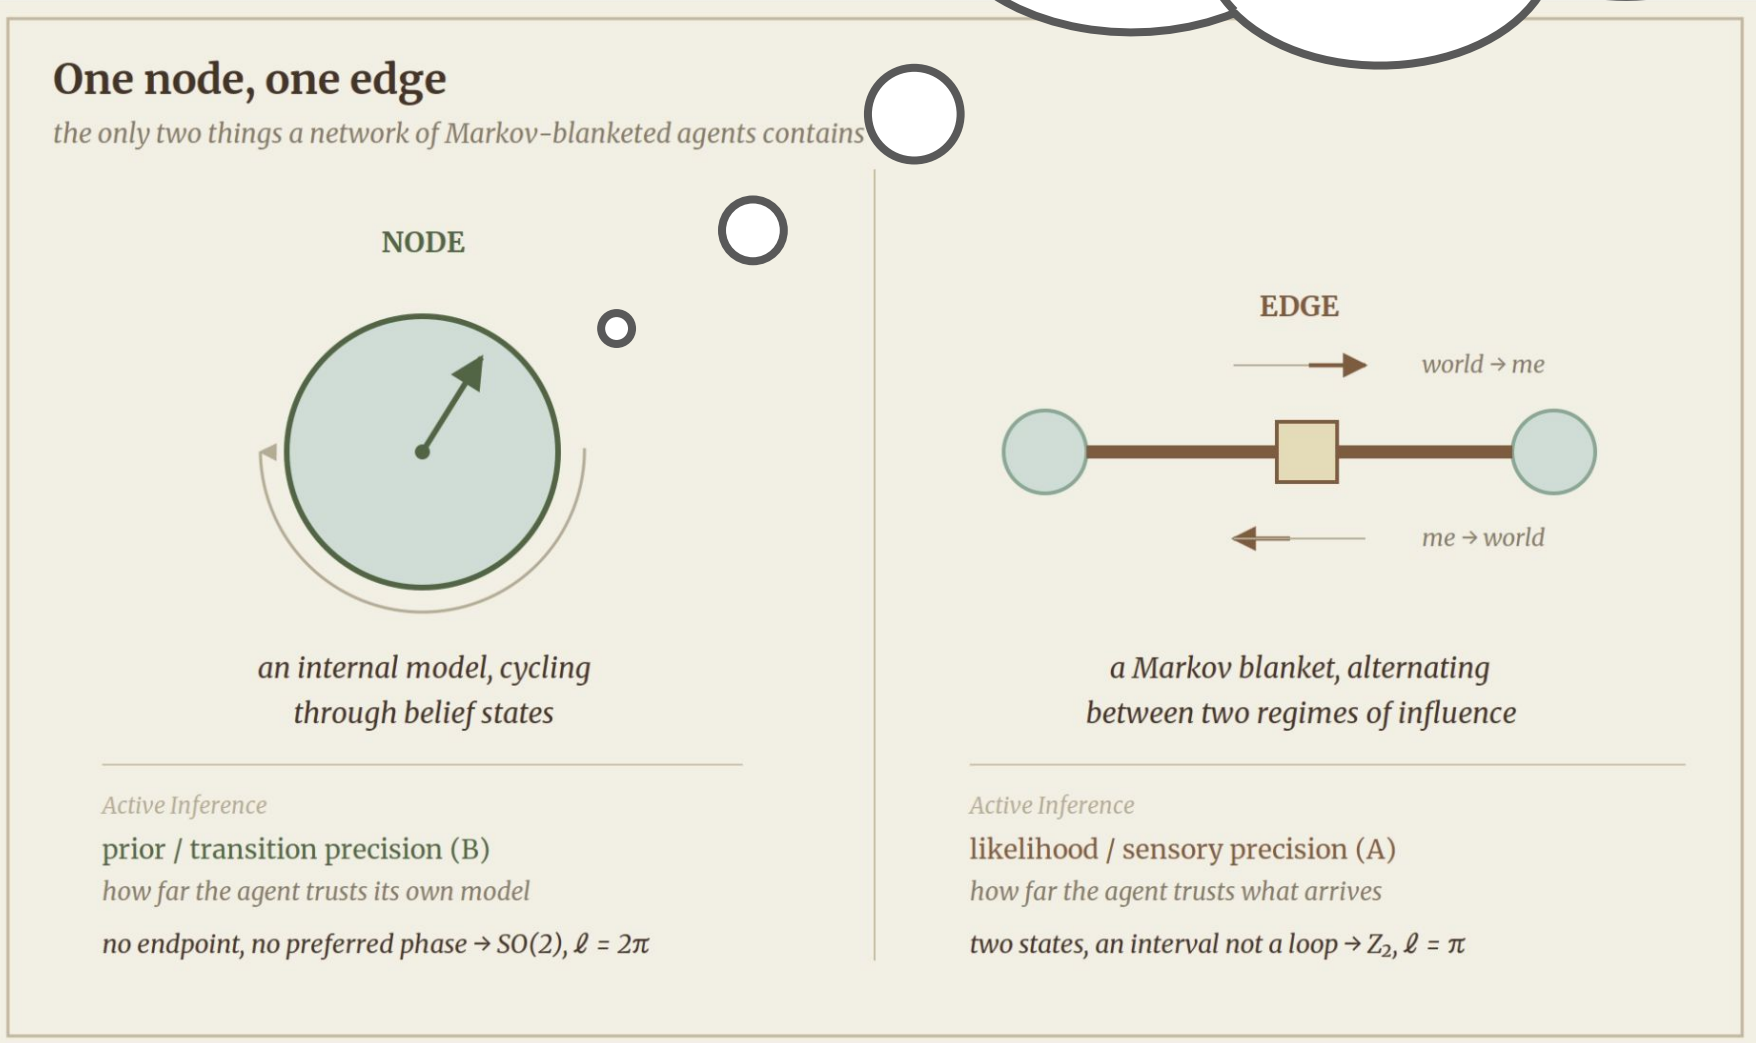

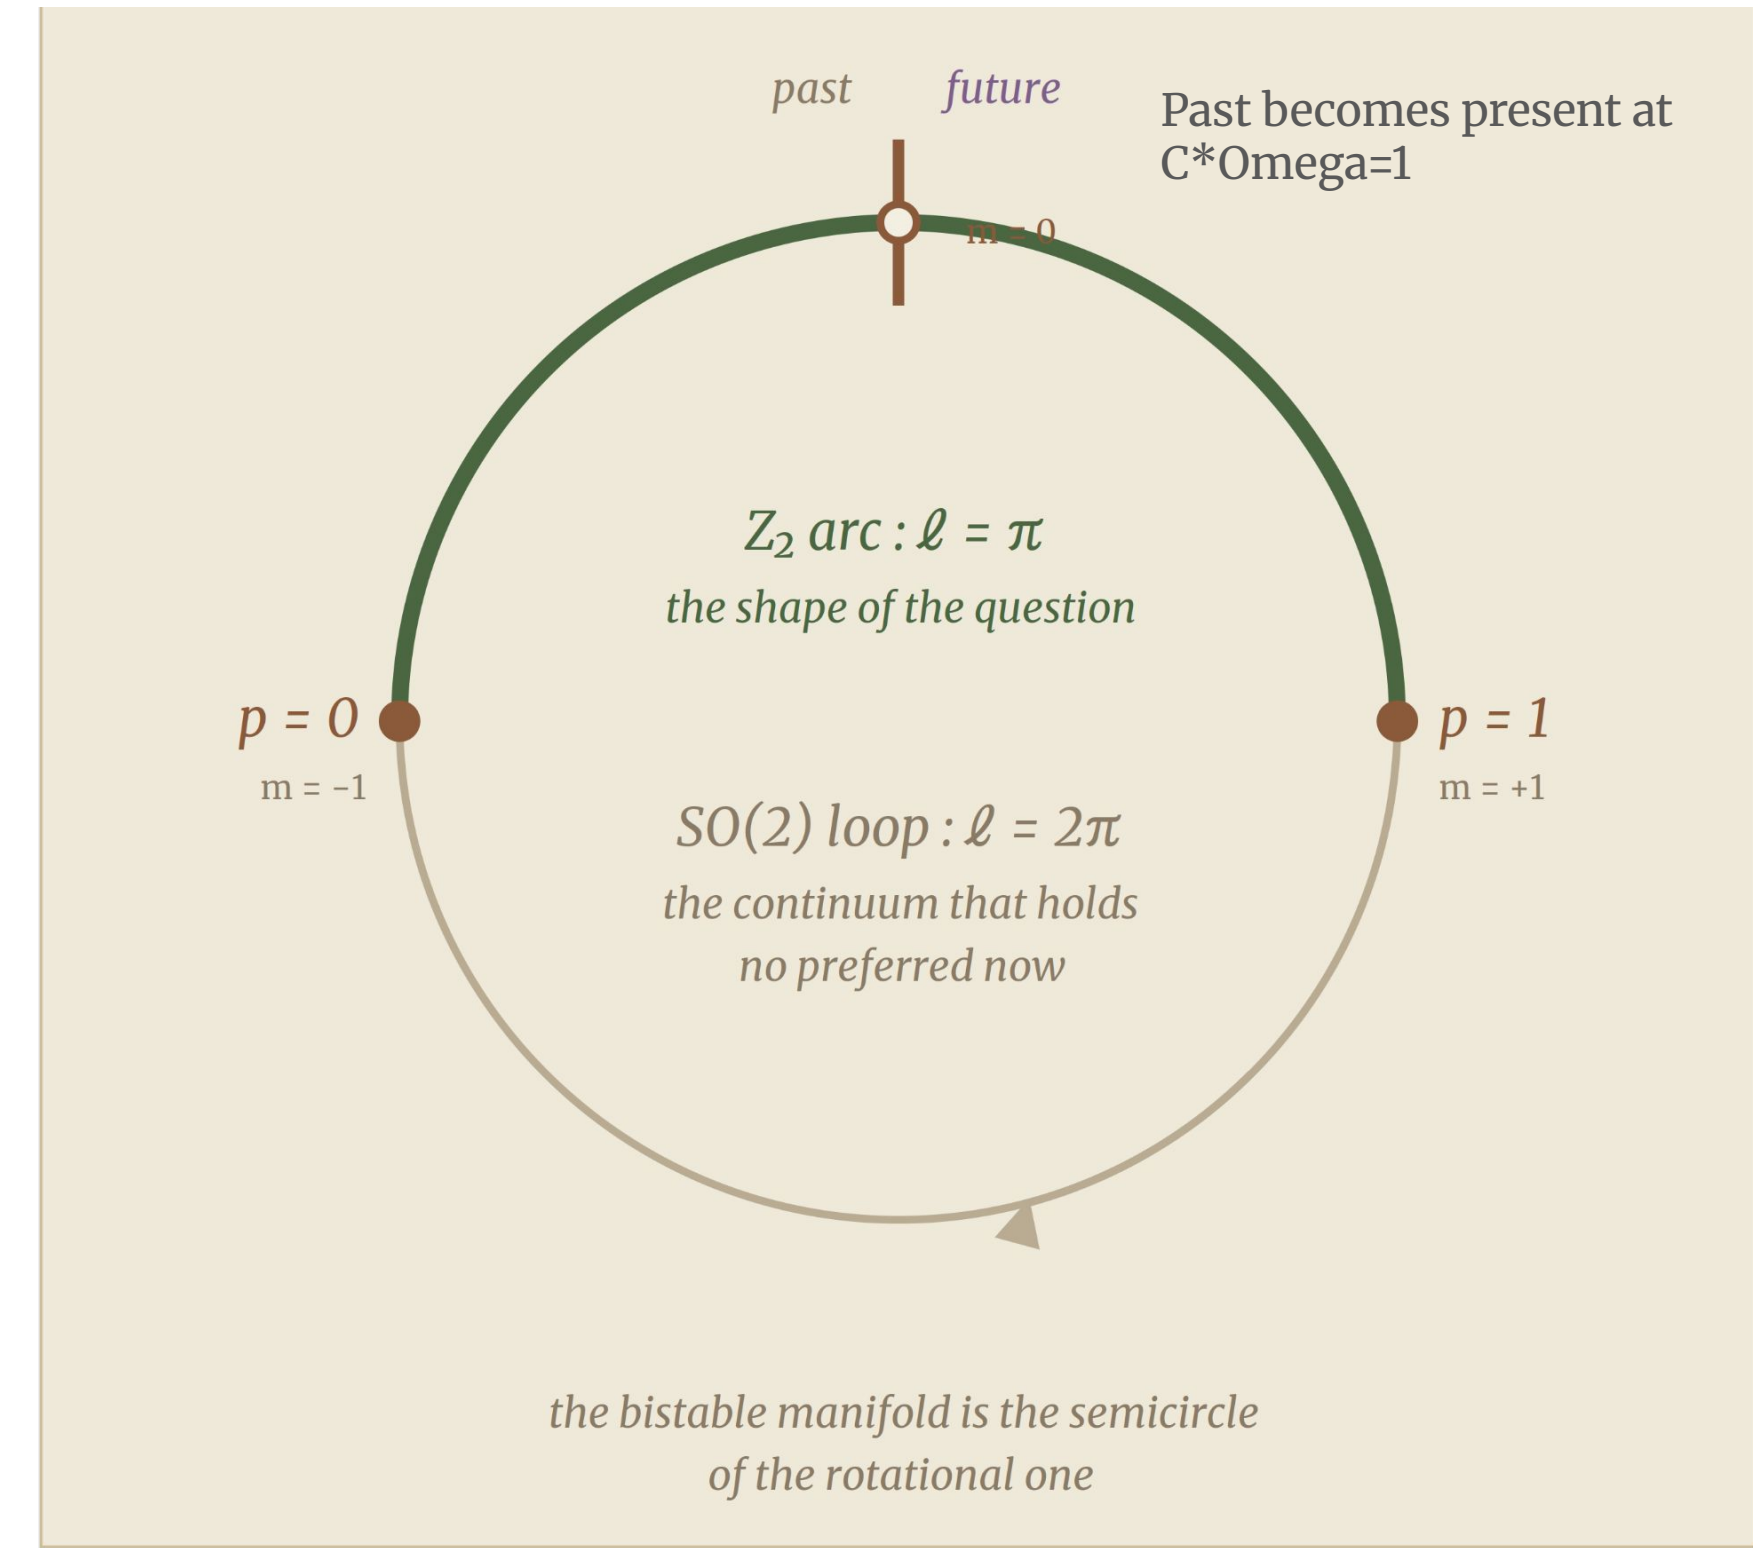

Dynamic CRR (Omega as free variable)

Low Ω vs High Ω : The system's coherence capacity dictates whether it remains locked in rigid habits or gains the flexibility to explore new trajectories.

- Persistence implies accumulation**
To persist is to find what works and hold it. Free energy falls as coherence rises.
- Finite capacity implies rupture**
Nothing finite accumulates without bound. Otherwise it would be everywhere, at once.
- Reconstruction is weighted by history**
After the cut, only the past has content. It is prehended, not replayed.
- The system has a characteristic variance**
One number sets capacity, rupture frequency and memory breadth. Read off, never fitted.
- Rupture is a maximum-entropy event**
At the cut the system knows nothing of what comes next. That is what pins the thresholds.

Geometric CRR (Omega as fixed variable)

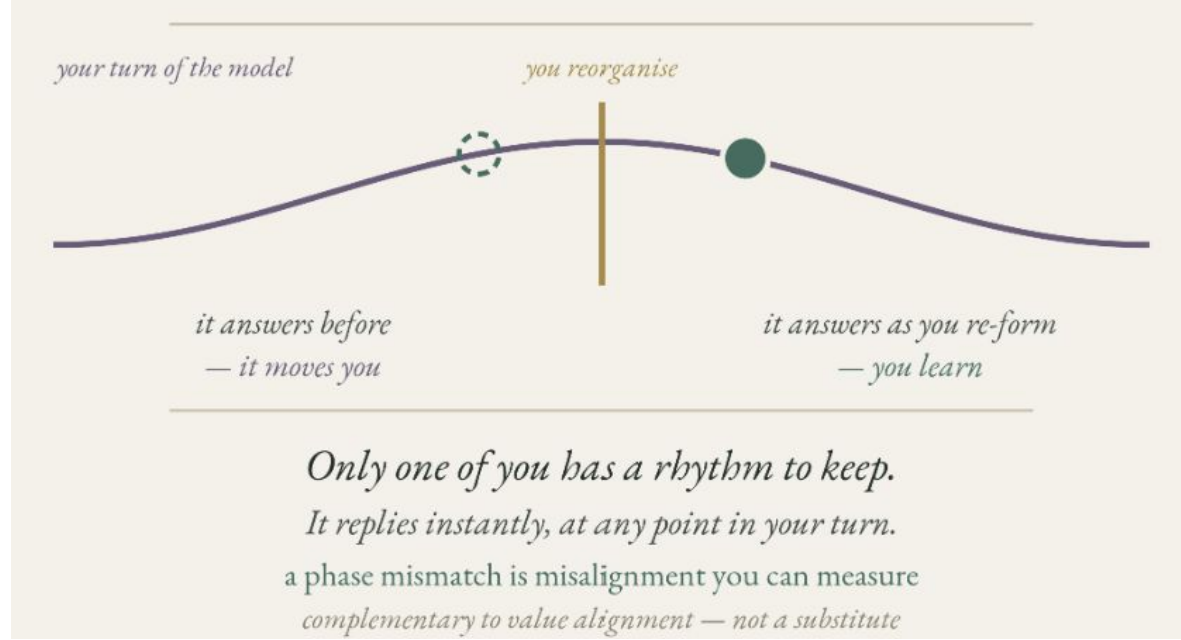

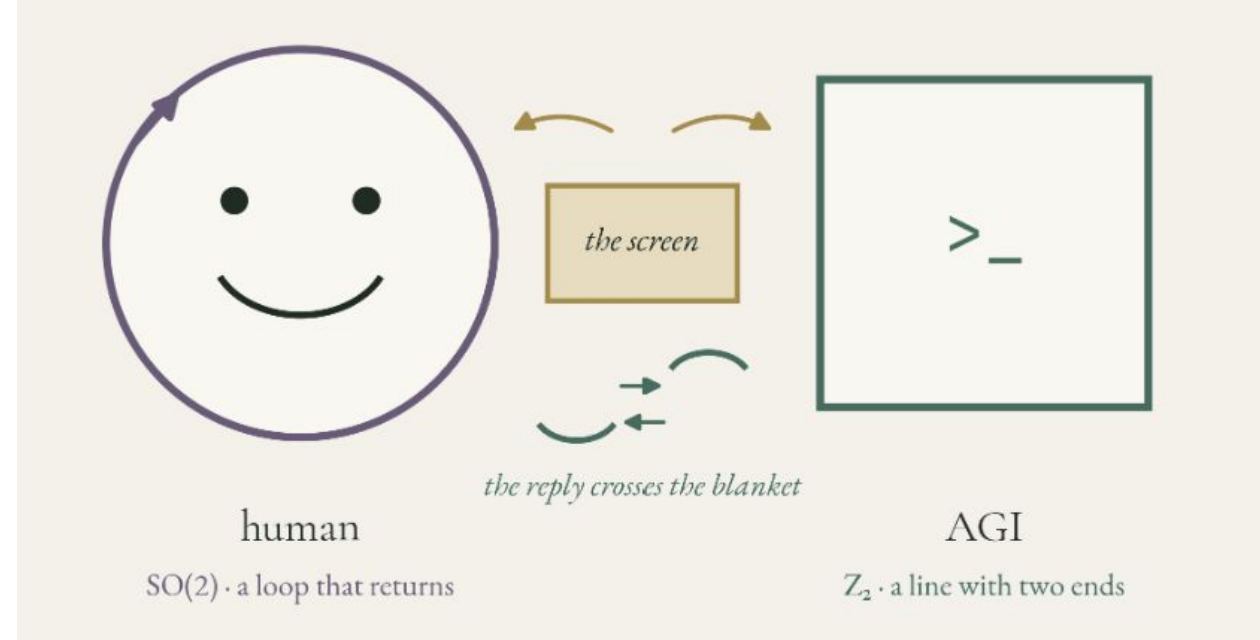

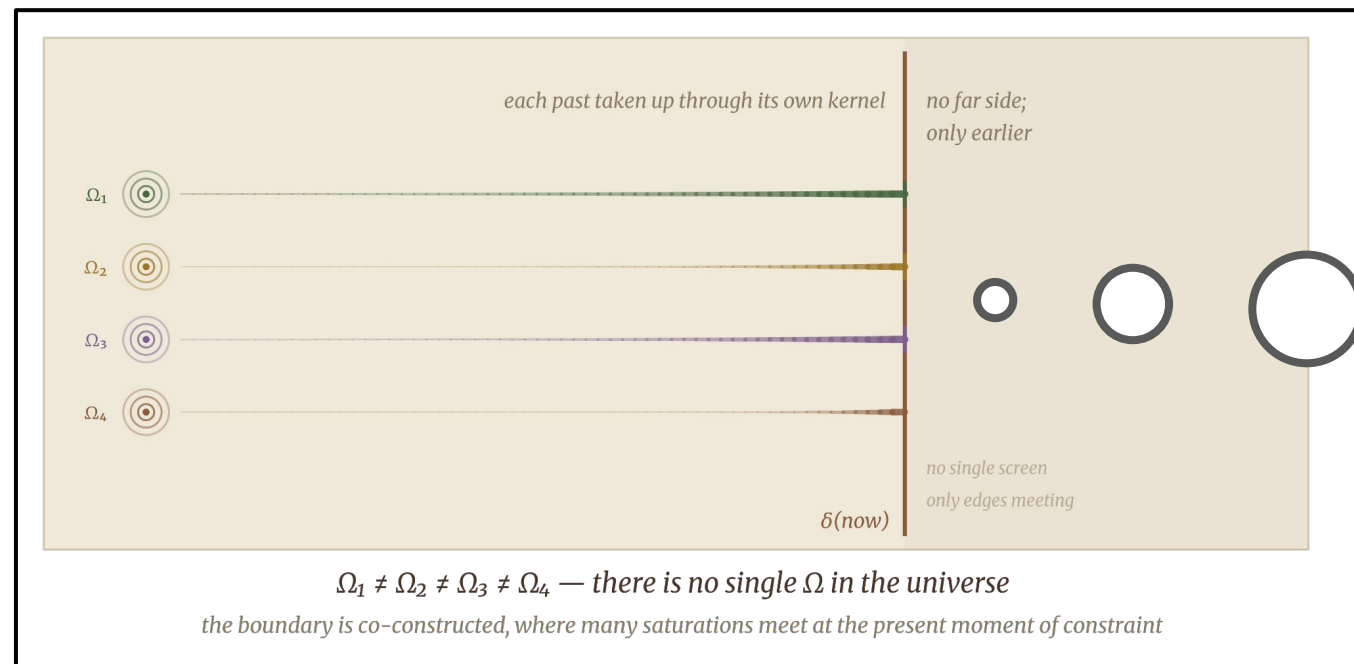

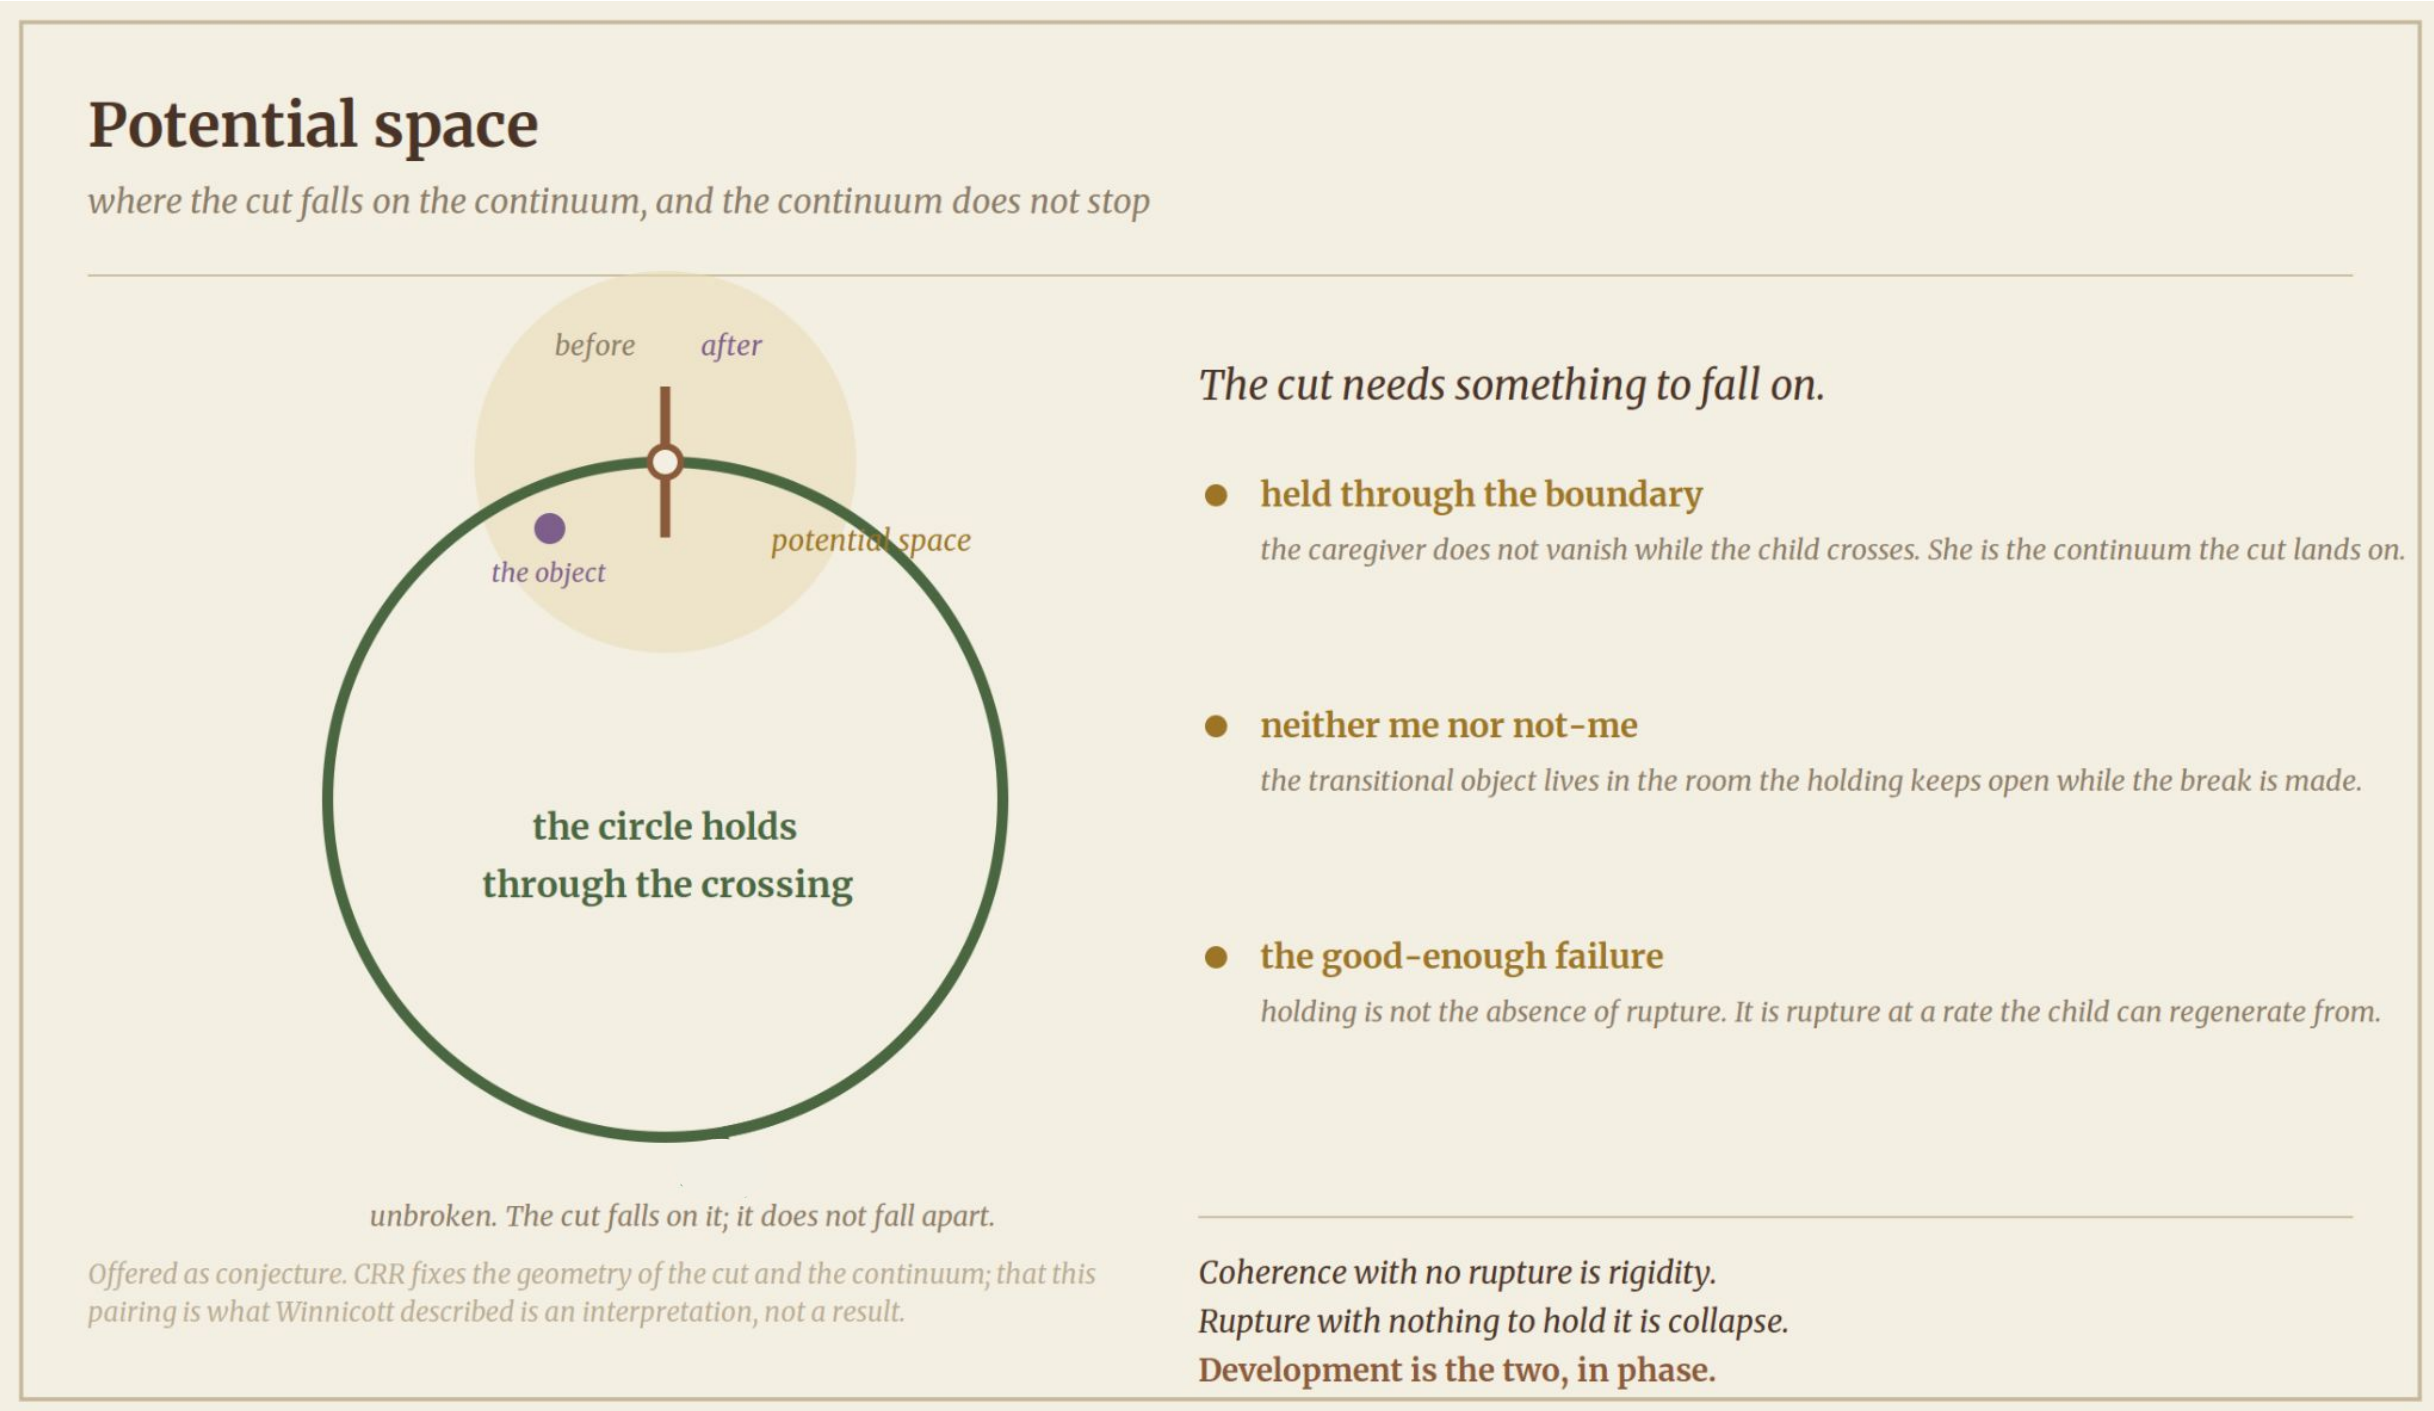

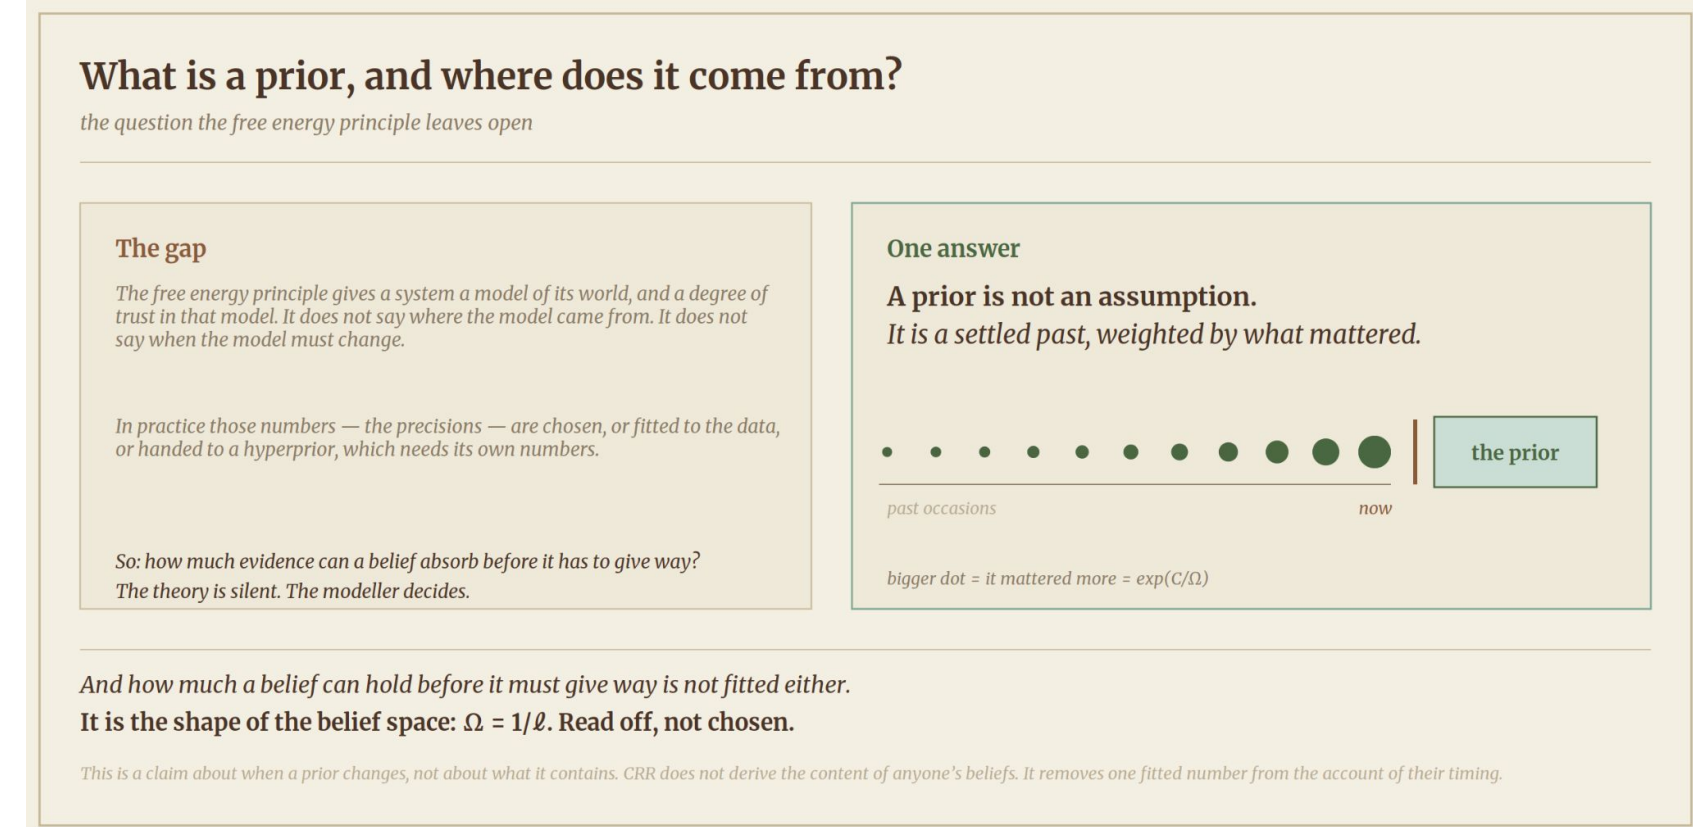

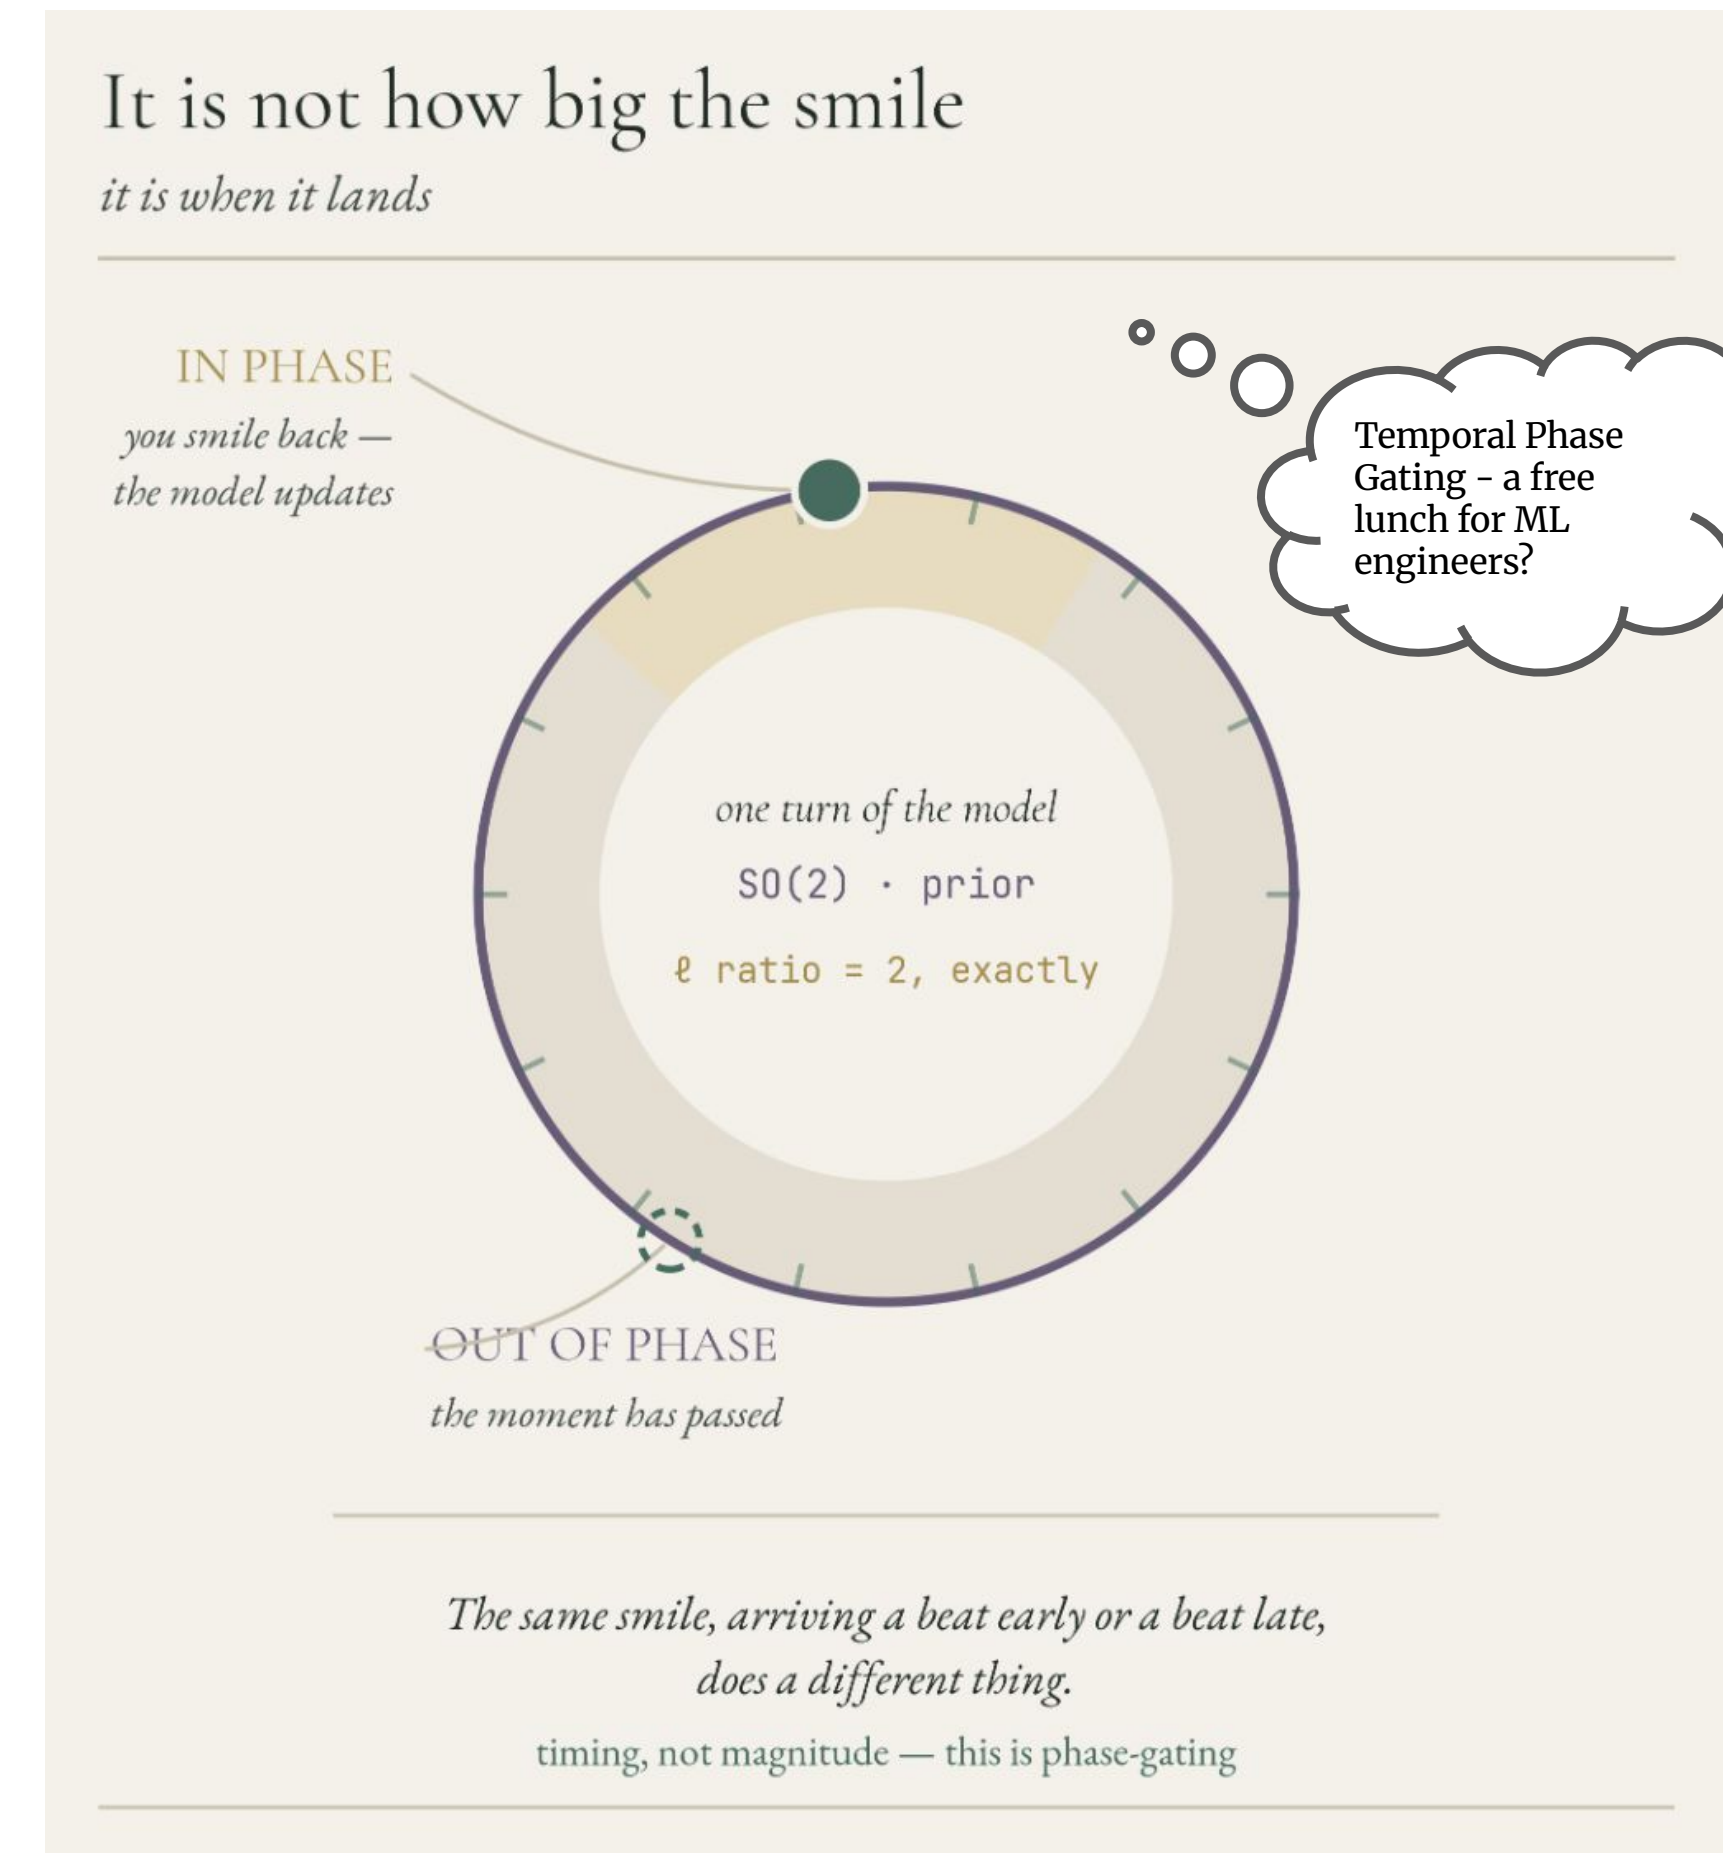

$\Omega = 1/\ell$ Cencov: the Fisher metric is the only one. ℓ is a topological invariant — nothing is fitted.

	ℓ	$\Omega = 1/\ell$	C^*	CV
Z_2 · bistable, the arc	π	$1/\pi \approx .318$	π	$1/2\pi \approx .159$
$SO(2)$ · rotational, the loop	2π	$1/2\pi \approx .159$	2π	$1/4\pi \approx .080$

ratio $\ell SO(2) / \ell Z_2 = 2$, exactly — forced by the doubling

The shape of the question fixes ℓ , hence Ω ; it varies by system. The shape of the cut never varies. It is always Z_2 . The cut falls at $m = 0$: the fixed point of $m \rightarrow -m$, the maximum-entropy state at which rupture occurs.

System Coefficient of Variation Predictions

Hello! My name is Alexander Sabine. My professional history is in child development and humanities. I want to better understand what AGI really means for us. Thank you. I am honoured to be among you all.
